Villa-Abrille MC, Cingolani E, Cingolani HE, Alvarez BV. Silencing of cardiac mitochondrial NHE1 prevents mitochondrial permeability transition pore opening. Am J Physiol Heart Circ Physiol 300: H1237–H1251, 2011. First published February 4, 2011; doi:10.1152/ajpheart.00840.2010.—Inhibition of Na+/H+ exchanger 1 (NHE1) reduces cardiac ischemia-reperfusion (I/R) injury and also cardiac hypertrophy and failure. Although the mechanisms underlying these NHE1-mediated effects suggest delay of mitochondrial permeability transition pore (MPTP) opening, and reduction of mitochondrial-derived superoxide production, the possibility of NHE1 blockade targeting mitochondria has been incompletely explored. A short-hairpin RNA sequence mediating specific knock down of NHE1 expression was incorporated into a lentiviral vector (shRNA-NHE1) and transduced in the rat myocardium. NHE1 expression of mitochondrial lysates revealed that shRNA-NHE1 transductions reduced mitochondrial NHE1 (mNHE1) by ~60%, supporting the expression of NHE1 in mitochondria membranes. Electron microscopy studies corroborate the presence of NHE1 in heart mitochondria. Immunostaining of rat cardiomyocytes also suggests localization of NHE1 with the mitochondrial marker cytochrome c oxidase. To examine the functional role of mNHE1, mitochondrial suspensions were exposed to increasing concentrations of Ca2+ to induce MPTP opening and consequently mitochondrial swelling. shRNA-NHE1 transduction reduced Ca2+-induced mitochondrial swelling by 64 ± 4%. Whereas the NHE1 inhibitor HOE-642 (10 μM) decreased mitochondrial Ca2+-induced swelling in rats transduced with nonsilencing RNAi (37 ± 6%), no additional HOE-642 effects were detected in mitochondria from rats transduced with shRNA-NHE1. We have characterized the expression and function of NHE1 in rat heart mitochondria. Because mitochondria from rats injected with shRNA-NHE1 present a high threshold for MPTP formation, the beneficial effects of NHE1 inhibition in I/R resulting from mitochondrial targeting should be considered.

ischemia; myocardium; mitochondrial permeability transition pore

SARCLOMELAL Na+/H+ EXCHANGER 1 (NHE1) is a major Na+ influx pathway that catalyzes the electroneutral exchange of one intracellular H+ for one extracellular Na+ across the plasma membrane of cardiac cells. NHE1, which is relatively quiescent under basal conditions, becomes highly active during ischemia in response to intracellular acidosis, leading to NHE1-mediated Na+ entry across the plasma membrane of cardiac cells. NHE1, which is relatively quiescent under basal conditions, becomes highly active during ischemia in response to intracellular acidosis, leading to NHE1-mediated Na+ entry across the plasma membrane of cardiac cells. NHE1, which is relatively quiescent under basal conditions, becomes highly active during ischemia in response to intracellular acidosis, leading to NHE1-mediated Na+ entry across the plasma membrane of cardiac cells. NHE1, which is relatively quiescent under basal conditions, becomes highly active during ischemia in response to intracellular acidosis, leading to NHE1-mediated Na+ entry across the plasma membrane of cardiac cells. NHE1, which is relatively quiescent under basal conditions, becomes highly active during ischemia in response to intracellular acidosis, leading to NHE1-mediated Na+ entry across the plasma membrane of cardiac cells. NHE1, which is relatively quiescent under basal conditions, becomes highly active during ischemia in response to intracellular acidosis, leading to NHE1-mediated Na+ entry across the plasma membrane of cardiac cells. NHE1, which is relatively quiescent under basal conditions, becomes highly active during ischemia in response to intracellular acidosis, leading to NHE1-mediated Na+ entry across the plasma membrane of cardiac cells. NHE1, which is relatively quiescent under basal conditions, becomes highly active during ischemia in response to intracellular acidosis, leading to NHE1-mediated Na+ entry across the plasma membrane of cardiac cells. NHE1, which is relatively quiescent under basal conditions, becomes highly active during ischemia in response to intracellular acidosis, leading to NHE1-mediated Na+ entry across the plasma membrane of cardiac cells. NHE1, which is relatively quiescent under basal conditions, becomes highly active during ischemia in response to intracellular acidosis, leading to NHE1-mediated Na+ entry across the plasma membrane of cardiac cells. NHE1, which is relatively quiescent under basal conditions, becomes highly active during ischemia in response to intracellular acidosis, leading to NHE1-mediated Na+ entry across the plasma membrane of cardiac cells. NHE1, which is relatively quiescent under basal conditions, becomes highly active during ischemia in response to intracellular acidosis, leading to NHE1-mediated Na+ entry across the plasma membrane of cardiac cells. NHE1, which is relatively quiescent under basal conditions, becomes highly active during ischemia in response to intracellular acidosis, leading to NHE1-mediated Na+ entry across the plasma membrane of cardiac cells.
membrane and mitochondria, has been documented previously. In addition, connexin 43 (Cx43), a constitutive protein that forms cardiac gap junctions contributing to cell-cell coupling, was also localized in mitochondria (8, 9). Cx43 contains four transmembrane domains as well as amino and carboxy termini located in the cytosol. Cx43 localized in subarcoclemal mitochondrial with its carboxy terminus directed towards the intermembrane space (9). Following this line of thinking, we reason that NHE1 would be involved in the Na\(^+\)/H\(^+\) exchange process in the mitochondria.

To our knowledge, NHE1 function and expression has not been evaluated in cardiac tissues with the assistance of the RNA interference (RNAi) technique. In vivo experiments were performed injecting a lentiviral vector expressing short-RNA-NHE1 intramyocardially, with the objective of knocking down the expression of NHE1 in the heart. Transduction of short-RNA-NHE1 allowed us to assess the expression and functional role of NHE1 at the subcellular level in the rat heart.

We revealed the expression of NHE1, a typical integral plasma membrane protein, in the heart mitochondria. Furthermore, we demonstrated that inhibition of NHE1 protects heart mitochondria from Ca\(^{2+}\)-induced mitochondrial swelling and MPTP opening.

**MATERIALS AND METHODS**

Isolation of rat cardiomyocytes. Adult rats were anesthetized with euthanyl (pentobarbital sodium; 100 mg/kg ip). The hearts were rapidly removed, and ventricular myocytes were obtained by enzymatic dissociation using standard protocols (2). Animal protocols were reviewed and approved by the Animal Welfare Committee of La Plata School of Medicine and performed in accordance with the Guide for the Care and Use of Laboratory Animals, published by the National Institutes of Health, and the Argentine Republic Law No. 14346 concerning animal protection. The hearts were rapidly removed, and ventricular myocytes were obtained by enzymatic dissociation, using standard protocols (2).

Isolation of rat heart membranes. Rat heart membranes were prepared from freshly isolated left ventrices, which were separated and homogenized with a Brinkmann Homogenizer (Brinkmann Instruments, Westbury, NY) in 4 ml of ice-cold solution containing 0.32 M sucrose, 1 mM EGTA, 10 mM HEPES, pH 7.5, and protease inhibitors (MiniComplete tablets; Roche). Homogenates were centrifuged at 1,440 g for 5 min in a Beckman GS-6K centrifuge. Supernatants were removed and centrifuged at 66,700 g for 30 min at 4°C in a Beckman TLA 100.4 rotor. The resulting membrane fraction was resuspended in 300 μl of PBS containing (in mM): 140 NaCl, 3 KCl, 6.5 Na\(^2\)HPO\(_4\), and 1.5 KH\(_2\)PO\(_4\), pH 7.5. The QuantiT protein assay kit (Molecular Probes/Invitrogen Labeling and Detection, Eugene, OR) was used to determine protein concentration on a Qubit fluorometer (Invitrogen) according to the manufacturer’s instructions, and 100 μg of protein were used for immunoblots.

Isolation of rat heart mitochondria. Rat heart mitochondria were isolated by differential centrifugation, according to a modified method described previously (38). Briefly, hearts were rapidly excised from pentobarbital-anaesthetized rats and placed in an ice-cold isolation buffer (IB) containing (in mM): 75 sucrose, 225 mannitol, and 0.01 EGTA, pH 7.4. After both atria and right ventricle were removed, the atria and homogenized with a Brinkmann Homogenizer (20 strokes) in the presence of proteinase (0.8 mg in 5 ml of buffer H). The resulting homogenate was centrifuged for 10 min at 10,000 g, and the resulting pellet was further resuspended in 1 ml of buffer H and homogenized in a Dounce homogenizer to obtain the crude mitochondria. Briefly, 1 ml of the crude mitochondria suspension was loaded in a tube containing 9 ml of 30% (vol/vol) Percoll in buffer H and centrifuged for 30 min at 95,000 g in a 70.1 Ti rotor, in a Beckman LE-80K ultracentrifuge. After centrifugation, the tubes contained two distinct bands separated by a clear zone. The lower brownish band was collected and diluted fourfold in cooled buffer H. To remove the Percoll, the samples were centrifuged for 10 min at 6,300 g, and the pellet was washed two times with cold buffer H to obtain pure mitochondria. The whitish upper layers of the self-forming Percoll gradient were collected and diluted fourfold in cold buffer H. They were centrifuged at 10,000 g for 10 min, and the resulting pellet was washed two times with cold buffer H to obtain the mitochondrial-associated vesicle fraction. The supernatant of this centrifugation was centrifuged at 100,000 g for 1 h to obtain the membrane-associated mitochondrial (MAM) fraction.

Mitochondrial swelling determination. Mitochondrial swelling was measured as a decrease in the 90° light-scattering signal induced by the addition of either 50 μM CaCl\(_2\) or 200 μM CaCl\(_2\), which promotes the influx of solutes through the opened MPTP and decreases light scattering. After 5 min of preincubation at 37°C in a medium containing (in mmol/l) 120 KCl, 20 MOPS, 10 Tris-HCl, and 5 KH\(_2\)PO\(_4\), pH 7.4, 50 μM or 200 μM CaCl\(_2\) were added to induce MPTP opening (6, 40). The decrease in light scattering was detected with a temperature-controlled Aminco Bowman Series 2 spectrofluorometer operating with continuous stirring at excitation and emission wavelengths of 520 nm. Light-scattering decrease was calculated for each sample as the difference between the values before and after the addition of CaCl\(_2\). The experiments were performed in the absence and in the presence of the NHE1 inhibitor cinacrinparide (10 μM). The effect of the inhibitors was expressed as the percentage of decrease in light scattering compared with that induced by 200 μM CaCl\(_2\).

Double immunostaining of rat cardiac myocytes and human embryonic kidney 293 cells, and analysis by confocal microscopy. Freshly isolated adult rat cardiomyocytes were fixed on 22 × 22-mm laminin (30 μg/ml)-coated glass cover slips, or human embryonic kidney (HEK) 293 cells were fixed on poly-l-lysine (10 μg/ml)-coated glass cover slips, and incubated at 37°C for 30 min to allow attachment. Cells were rinsed with PBS and fixed in 4% (wt/vol) paraformaldehyde for 15 min at room temperature (myocytes, HEK 293 cells), followed by methanol fixation-permeabilization [myocytes, ice-cold 100% (vol/vol) methanol, 5 min at −20°C]. Myocytes were then washed with PBS and permeabilized with 0.1% Triton X-100 (vol/vol) in PBS for 15 min at room temperature, and HEK 293 cells were washed with PBS and permeabilized with 0.1% Triton X-100 (vol/vol) in PBS for 2 min at room temperature. After washing (2 × 5 min with PBS) and blocking (5% BSA in PBS, 20 min) were completed, myocytes or HEK 293 cells were incubated with a combination of primary rabbit polyclonal anti-NHE1 antibody (sc-28758, 1:500; Santa Cruz) and mouse anti-cytochrome c oxidase complex I (COXI) antibody (sc-58347, 1:2,000; Santa Cruz) (1:100 dilutions), followed by secondary chicken anti-rabbit conjugated to Alexa fluor 488 and chicken anti-mouse conjugated to Alexa fluor 594 (1:100 dilutions). Immunostained cells were mounted in Prolong anti-fade solution (Molecular Probes) and imaged with an Olympus Bx51.
laser-scanning confocal microscope (myocytes) or a Zeiss LSM-410 laser-scanning confocal microscope (HEK 293 cells). Images were acquired with an oil immersion ×60 objective, confocal aperture 0.2, zoom ×1.5 (numerical aperture 1.4, plan Apochromat) at a resolution of 0.5- to 0.7-µm field depth. Filtering was used to integrate the signal collected over four frames to decrease noise, with a frame size of 1,024 × 1,024 (myocytes, scan time of 3.2 s/frame) or a frame size of 520 × 520 (HEK 293 cells). Images were saved and visualized with the Fluoview 3.3 Software (myocytes) or the LSM Image Browser (HEK 293 cells).

**Colocalization analysis.** For the colocalization assay of isolated rat cardiomyocytes, images were obtained with the same settings of the confocal microscope, except for detector gain adjustments in the green channel that were performed to normalize saturation levels. Images were analyzed using the colocalization menu of the Image-Pro Plus software. Regions of interest (ROIs) covering the entire area of the cardiomyocyte were created, followed by the adjustment of the red channel lower threshold to exclude background staining from further analysis. The colocalization statistics were determined from the points included within ROIs and presented as Pearson’s correlation values that can vary between zero and one. Pearson’s correlation reflects the linear relationship between two variables. A correlation of zero means that there is no linear relationship between the variables, whereas a correlation of one indicates a perfect positive linear relationship.

**Protein expression.** Expression constructs for human hemagglutinin (HA) epitope-tagged NHE1-HA or rat AE3-HA (AE3fl) have been described previously (2). HEK 293 cells were individually transfected with NHE1-HA or AE3-HA cDNAs using Lipofectamine 2000 reagent. Cells were grown at 37°C in an air-CO2 (19:1) environment in DMEM medium supplemented with 5% (vol/vol) FBS and 5% (vol/vol) calf serum.

**Isolation of HEK 293 cell mitochondria.** Mitochondria-enriched fractions from HEK 293 cells were prepared for immunoblot analysis of NHE1-HA and AE3-HA expression in transfected cells. Cells grown in 100-cm² plates (Corning) to 80% confluence at 37°C and 5% CO2 were trypsinized and sedimented by centrifugation. The cell lysates were probed with rabbit anti-NHE1 antibody (1:1,000 dilutions) or goat anti-NHE1 antibody (1:1,000 dilutions) and collected with an Erlangshen ES 1000 W digital camera.

**Immunodetection.** Cell samples (50 µg protein), heart lysates (50 µg protein), heart mitochondrial lysates (50 µg protein for lysates and 100 µg protein for immunoprecipitates), HEK 293 mitochondria lysates, or Percoll-purified mitochondria were resolved by SDS-PAGE on 8–10% acrylamide gels, as indicated. Proteins were transferred to polyvinylidene fluoride membranes and then incubated with rabbit anti-NHE1, mouse anti-NHE1 (MAB3140, 1:2,000; Chemicon), goat anti-NHE1 (sc-16097, 1:1,000; Santa Cruz), rabbit anti-

**Immunoprecipitation.** Homogenates of rat ventricles were centrifuged at 1,440 g for 5 min in a Beckman GS-6K centrifuge. Supernatants (4 mL corresponding to a total of ~2 mg of protein of heart lysates) were removed and applied to 50 µl protein A-Sepharose (50% slurry) for 3 h at 4°C. After centrifugation (5 min, 8,000 g), lysates were incubated overnight with rabbit polyclonal anti-NHE1 antibody (6 µl, 1.2 µg IgG) or nonimmune rabbit serum (6 µl). Resin was washed consecutively with wash 1 (0.1% Igepal, 1 mM EDTA, 0.15 M NaCl, and 10 mM Tris-HCl, pH 7.5), wash 2 (2 mM EDTA, 0.05% SDS, and 10 mM Tris-HCl, pH 7.5), and wash 3 (2 mM EDTA and 10 mM Tris-HCl, pH 7.5). After centrifugation (2,000 g), resin was resuspended in an equal volume of 2× SDS-PAGE sample buffer. Samples were electrophoresed on 8% acrylamide gels. Immunoblots were probed with rabbit anti-NHE1 antibody (1:1,000 dilutions) or goat anti-NHE1 antibody (1:1,000 dilutions).

**Tissue preparation, postembedding immunohistochemistry, and electron microscopy analysis.** Rat papillary muscles excised from left ventricles were harvested in 0.1 M phosphate buffer (PBS, pH 7.4) and fixed for 2 h with 2% glutaraldehyde at 4°C. Also, isolated heart mitochondria were fixed for 2 h in 2% glutaraldehyde fixative. After fixation, the cells and tissue blocks were rinsed with PBS and postfixed with 1% osmium tetroxide (2 h, 4°C). Tissues were then dehydrated, infiltrated, and included in Epoxy resin for 36 h subsequently at 35, 45, and 60°C to allow polymerization. Ultrathin sections (60 nm thick) were cut with a Reichert-J Super Nova microtome and collected on copper grids. After being washed with PBS containing 0.2% gelatin (PBSG), papillary muscle sections included on copper grids were permeabilized with 0.5% Triton X-100 in PBSG for 15 min at room temperature. Sections were blocked with 5% BSA in PBSG for 15 min at room temperature and labeled with the rabbit anti-NHE1 IgG antibody in PBSG (1:50 dilution, 14–16 h at 4°C). After being washed with PBSG buffer, samples were incubated with protein A conjugated to 14-nm gold particles (1:20 dilution) in PBSG. As controls, the primary antibody was omitted. After immunohistochemistry, samples were finally contrasted with lead citrate (1%) and uranyl acetate (1%) and viewed with a JEOL JEM 1200-EXII Electron Microscope. Micrograph images were captured and collected with an Erlangshen ES 1000 W digital camera.

**Construction and production of lentiviral vectors.** A third-generation lentiviral vector capable of expressing a reporter gene under the CMV promoter and shRNA under the RNA polymerase III H1 promoter was constructed as previously described (14). Briefly, the NHE1 shRNA was subcloned into a third-generation lentiviral vector plasmid that expresses DsRed under the CMV promoter and shRNA under the RNA polymerase III H1 promoter (PPT.C.DsRed.H1). The shNHE1 short-hairpin RNAi sequence was constructed inserting 5'-GATAGGTTTCCATGTGATC-3' (positive strand), followed by 5'-GTTCCTTCAGAGAGAC-3' (loop), 5'-ATCACATGGAAACCTATC-3' (negative strand), and 5'-ATCACATGAAACCTATC-3' (terminator) at the BamHI cloning site (5') and PacI cloning site (3'), following the H1 RNA Polymerase promoter, to generate PPT.C.DsRed.H1.shNHE1. The shSCR short-hairpin RNAi sequence was constructed inserting a noncoding, disorganized nucleotide sequence at the cloning site. For viral vector production, HEK 293T cells were plated in T75-cm² flasks to obtain 80–90% confluency on the day of transfection, and cotransfected with a four-plasmid vector system, using Lipofectamine 2000 (Invitrogen). The crude viral suspension was harvested from 293T cell cultures 48 and 72 h after transfection, filtered (0.2 µm) and concentrated using Centrifuge Plus-70 filter columns (100,000 molecular weight cut-off; Millipore) at 70,000 g (2 h, 8°C) (7). Vector aliquots were subsequently stored at −80°C until use. Vector titers were determined measuring fluorescence of positive HEK 293 cells, transduced with serial viral dilutions in 293T cells, in the presence of 10 µg/mL of polybrene (Sigma).

**Injection of lentiviral vector and transduction efficiency analysis.** We elected to deliver a small-hairpin RNA (shRNA) targeting rat heart NHE1 (shRNA-NHE1) to downregulate the expression of...
mNHE1. This sequence, which was proven effective in reducing whole NHE1 protein expression in cultured fibroblasts, was used here (1). Four- to five-month-old male Wistar rats underwent left thoracotomy in the fourth or fifth intercostal space under general anesthesia, isoflurane inhalation, 4% for induction and 2.5% for maintenance, used in a gas mixture with oxygen and delivered through ventilation by using a positive-pressure respirator (model 680; Harvard, South Natick, MA). The heart was exposed, and the PTC.CDsRed.H1.shNHE1 lentivirus (~2 × 10^7 transducing units in 200 μl volume, multiplicity of infection ~80) was injected at two sites in the anterolateral wall of the left ventricle using a 30-gauge needle (n = 4) (7). As a control, normal rats were injected with 200 μl of saline solution (sham) at the left ventricle (n = 5). After injection, the lungs were inflated by increasing positive end-expiratory pressure, and the thoracotomy site was closed in layers. Immediately after surgery, rats were returned to their cages and carried to a recovery room of our faculty animal facility until death (2 wk or 1 or mo later). Rats had ad libitum access to food and water. Two weeks after injections, hearts were removed, and mitochondria were prepared from left ventricles as described in previous sections. To evaluate transduction efficiency, isolated cardiomyocytes from injected animals were fixed to 30 μg/μl laminin-coated glass cover slips, mounted on glass slides, and evaluated by fluorescence microscopy for DsRed fluorescence.

Statistical analysis. All results are presented as means ± SE. Significance of differences between any two groups was determined by the Student’s t-test or ANOVA. A final value of P < 0.05 was considered significant for all analyses. All probability values reported are two-sided.

RESULTS

Distribution of the NHE1 Na^+/H^+ exchanger in isolated cardiomyocytes. To determine the cellular location of NHE1 in the intact rat myocardium, we used confocal immunofluorescence microscopy analysis of isolated adult rat cardiomyocytes, using an isoform-specific rabbit polyclonal anti-NHE1 antibody that recognizes human NHE1. Rat NHE1 has a high degree of sequence similarity with human NHE1 and was therefore anticipated to react with the anti-human NHE1 antibody. NHE1 protein expression was localized predominantly to the intercalated disc regions, with less prominent labeling of transverse tubules (Fig. 1A, left), as shown in previous reports (52). Within the cell, a longitudinal punctuate labeling of NHE1, reminiscent of organelles such as mitochondria, was observed. Therefore, we performed double-labeling experiments of rat cardiomyocytes using anti-COXI antibody, a mitochondrial protein, and anti-NHE1 antibody. NHE1 colocalized with COXI to some extent (merged images), suggesting expression of NHE1 in mitochondria (Fig. 1A, left). No fluorescent signal was detected in cardiomyocytes treated with secondary antibodies alone (Fig. 1A, right). Quantification analysis was performed in isolated cardiomyocytes double-labeled with anti-NHE1 and anti-COXI antibodies. Line scans of the images show a certain degree of overlapping between NHE1 (green) and COXI (red), also observed in a three-dimensional image view, suggesting colocalization of both proteins (Fig. 1B). The quantification of the colocalization of green channel pixels (NHE1) with red channel pixels (COXI) was performed using the “colocalization” function of the image analysis software Image-Pro Plus. The association degree of NHE1 with the mitochondrial inner membrane marker COXI is depicted as a Pearson’s correlation coefficient (r) (Fig. 1C) where the r values between −0.3 ± 0.3 indicate little or no association, +0.3 ± 0.7 weak positive association, and +0.7 ± 1.0 strong positive association. Using this analysis, we found that NHE1 shows a high degree of colocalization with COXI (r = 0.75 ± 0.01, n = 13; see Fig. 4B), suggesting the localization of NHE1 to the subcellular mitochondria of the rat myocardium.

Expression of the NHE1 Na^+/H^+ exchanger in rat heart mitochondria. To determine the role of the NHE1 in the heart mitochondria, we examined the expression of NHE1 in deenergized mitochondria isolated from normal adult rat left ventricular myocardium. The purity of mitochondrial fractions obtained from rat heart was assessed by electron microscopy (EM). Electron micrographs showed well-preserved elliptical-shaped mitochondria with intact inner and external mitochondrial membranes (Fig. 2A). Expression of NHE1 protein was studied in purified rat heart mitochondria lysates by immunoprecipitation. NHE1 was immunoprecipitated using rabbit anti-NHE1 antibodies, and corresponding immunoblots were probed with either rabbit anti-NHE1 antibody (Fig. 2B) or goat anti-NHE1 antibody (Fig. 2C). Both antibodies recognized NHE1 in mitochondrial lysates and immunoprecipitates, and NHE1 expression analysis (AU/μg protein, n = 3) was performed (Fig. 2D). Importantly, nonimmune rabbit serum failed to immunoprecipitate NHE1 from mitochondrial lysates (Fig. 2, B and C). To verify these results, cardiac mitochondrial lysates were analyzed together with HEK 293 lysates, which endogenously express low levels of the NHE1 protein. Both lysates were electrophoresed, and corresponding immunoblots were probed with mouse monoclonal anti-NHE1 antibody (Fig. 3A). Immunoblots revealed bands with the same electrophoretic mobility for both lysates. Mitochondrial preparations may contain some membrane contaminants that could affect previous conclusions. To exclude this possibility, markers of the plasma membrane (Na^+-K^+-ATPase), cellular recycling endosomal compartment (TIR), or mitochondria (COXI) were blotted and probed with specific antibodies. HEK cultured whole cell lysates, used as positive controls, expressed Na^+-K^+-ATPase (A), TIR (B), and COXI (C) proteins, to some extent. Immunoblots shown on Fig. 3, B–D, confirmed that the mito-
chondrial lysates used for immunoprecipitation and immuno-blotting experiments were enriched in mitochondria, without other major cellular contaminants. A small but detectable fraction of dense endosomes containing TfR was observed in the heart mitochondrial preparation (Fig. 3B).

All NHE1 antibodies used herein are specific antibodies directed against the COOH-terminal domain of NHE1. Whereas the mouse anti-NHE1 antibody targets the entire (~300 amino acids) COOH terminus of NHE1, rabbit anti-NHE1 and goat polyclonal anti-NHE1 antibody (Goat a-NHE1, C) recognize the last 160 amino acid and last 20 amino acid epitopes of the NHE1 cytoplasmic COOH-terminal tail, respectively, targeting NHE1 and not other NHE isoforms (Fig. 4).

In additional experiments, we examined the expression of NHE1 in Percoll-purified mitochondria on immunoblots. Expression of NHE1 was observed in crude and pure mitochon-
drial lysates but not in MAM lysates (Fig. 5A).

To determine if NHE1 is targeted to mitochondria as predicted, dual-labeling experiments were carried out in HEK 293 cells, which express endogenous NHE1, using a mitochondrion-specific marker, COXI, and specific anti-NHE1 antibody. As demonstrated in a cluster of HEK cells (Fig. 5B), the red fluorescence from the COXI was found primarily in clusters of punctuate extranuclear sites, consistent with mitochondrial localization. The green signal emitted by NHE1 protein accumulates in the surface of the cell and as a punctuate labeling in different subregions of the cell. Colocalization of signals from COXI and NHE1 is indicated in yellow/orange when the red and green scans are overlaid (Fig. 5B). This pattern represents the staining seen in all experiments. These data suggest that, in addition to plasma membrane localization, NHE1 is most likely targeted to the mitochondria of HEK 293 cells.

The subcellular distribution of NHE1 was also studied in HEK 293 cells individually transiently transfected with NHE1-HA or a HA-epitope tag AE3 anion exchanger cDNA. Mitochondria were isolated from HEK 293 cells transfected with NHE1-HA or AE3-HA, and mitochondrial lysates were resolved by SDS-PAGE, blotted, and probed with anti-HA antibody, or anti-COXI antibody (Fig. 5C). HEK 293 mitochondria expressed NHE1-HA, which extends the finding of subcellular NHE1 expression to other cell types. However, AE3, a protein localized in sarcolemma, T tubules, and sarco-

---

Fig. 2. Immunoprecipitation of NHE1 from rat heart mitochondria. A: electron micrographs of mitochondria isolated from rat left ventricles. External and inner mitochondrial membranes are easily distinguished at higher magnification (bottom). Bar = 500 nm. B and C: a total of 300 μg protein of rat ventricular mitochondrial lysates (Lys) were immunoprecipitated (IP) with rabbit antibody directed against NHE1 (Rb a-NHE1) or with irrelevant rabbit nonimmune serum (NIS) and resuspended in a final volume of 100 μl. Gels were loaded with lysates corresponding to 50 μg of protein and 150 μg of immunoprecipitated protein (50 μl). Mitochondria lysates (Lys and IP) underwent SDS-PAGE, were transferred to a polyvinylidene difluoride (PVDF) membrane, and were probed on with Rb a-NHE1 (B) or goat polyclonal anti-NHE1 antibody (Goat a-NHE1, C). Position of NHE1 is shown (filled arrows). D: quantification analysis of immunoblots. NHE1 protein expression corresponding to heart mitochondria lysates and immunoprecipitates is shown as densitometry (AU, arbitrary units) per μg of protein (n = 3).
plasmic reticulum of cardiomyocytes (3), and predominantly at the cell surface of HEK 293-transfected cells (13), was not found in mitochondrial lysates. Colocalization signals of NHE1-HA-transfected or AE3-HA-transfected HEK 293 cells with endogenous COXI were quantified with the Image-Pro Plus software (data not shown). NHE1-HA showed a strong positive association degree with COXI (r = 0.70 ± 0.07, n = 4), whereas AE3-HA was weakly associated with COXI (r = 0.31 ± 0.06, n = 5), demonstrating again localization of NHE1-HA to the subcellular mitochondria of the HEK cells. Taken together, these experiments demonstrate the expression of NHE1 protein in mitochondria isolated from rat ventricular myocardium and mitochondria isolated from HEK 293 cells transfected with NHE1-HA cDNA.

Proteins localized in mitochondria have a mitochondrial localization signal in their NH2 terminus. The mitochondrial localization prediction program, MITOPROT Software, was used to evaluate the probabilities of NHE1 mitochondrial localization. The amino acid sequences for the human NHE family members, human COXI, and human Na+/K+-ATPase α2-subunit were retrieved from the Swiss Prot database and analyzed by MITOPROT (Table 1). There is a strong prediction for mitochondrial localization of NHE1 (86%), and NHE6 (99%), and to a lesser extent for NHE3 (59%), but not the other NHE isoforms. Indeed, the mitochondrial localization probability for NHE1 and NHE6 was similar to that of the human mitochondrial protein COXI (98%). NHE6 has been recently identified in early/recycling endosomes and stereocilia of sensory hair cells (10, 29). Consistent with its plasma membrane localization, Na+/K+-ATPase α2-subunit has a low mitochondrial localization prediction (32%). Interestingly, all vertebrates share high prediction of NHE1/nhe1 localization to mitochondria, ranging from 0.46 (birds, lowest) to 0.96 (fish, highest), and from 0.53 (pig, lowest) to 0.89 (rabbit, highest) among mammals (Table 2).

Subcellular localization of NHE1 and COXI in the myocardium. There is no evidence, to our knowledge, of high-resolution immunogold analysis of any NHE isoform localized to the mitochondria. Herein, we explored the subcellular localization of NHE1 and COXI in rat left ventricular papillary muscle sections studied in detail, using immunogold EM. The advantage this method provides is that it examines at a very high resolution the location of the protein in the ultrastructure, as it exists in a normal cell or tissue. For this purpose, rat papillary muscle sections were probed with rabbit anti-NHE1 antibody, or mouse anti-COXI antibody, followed by detection with protein A conjugated to 14-nm gold particles. A total of 12 grids were analyzed for each protein. In the heart sections, labeling of NHE1 was clearly observed in mitochondria, at low- and high-power magnifications (Fig. 6, A, B, and E). Gold particles were quantified, and an average of 3.46 ± 1.12 particles were observed (20 grids, 10 mitochondria/grid). Mitochondria presented a minimum of 1 particle and a maximum of 25 particles, corresponding to NHE1 expression. Labeling of COXI was also observed in the mitochondria (Fig. 6, C and F), whereas muscle sections treated only with protein A gold conjugated did not display any gold particles and were therefore immunonegative (Fig. 6D). The localization of immunogold particles suggests the existence of both NHE1 and COXI in the rat heart mitochondria.

Cardiomyocytes contain subsarcomembranous (SSM) and interfibrillar (IFM) mitochondria, which differ in their respiratory and Ca2⁺ retention capacity. In our immunogold analysis of NHE1 expression in cardiac muscle mitochondria, we clearly identified NHE1 in IFM (Fig. 6, A and B). We could not, however, exclude the expression of NHE1 in the SSM population of cardiomyocytes.

We conclude that NHE1 is present in the myocardium and located in cardiomyocyte mitochondria.

Knock down of mNHE1 from ventricular myocardium. We also used biochemical approaches to assess NHE1 expression in mitochondria. We prepared mitochondrial fractions from 4-month-old rat hearts and examined them for protein expression of NHE1 and Ca2⁺-induced mitochondrial swelling.

PPT.C.DsRed.H1.shNHE1 transduced hearts expressed the DsRed transgene product 14 days after vector transduction, whereas cardiomyocytes of sham-injected animals showed no fluorescence signals (Fig. 7A). DsRed labeling was seen in 80 ± 5% of the rod-shaped cardiomyocytes attached to the cover slips (n = 1, 6 cover slips and ~250 myocytes analyzed), which demonstrated the transduction efficiency of shRNA-NHE1 delivered by intramyocardial lentivirus injections. Left ventricular mitochondrial lysates were resolved by SDS-PAGE, blotted to polyvinylidene difluoride membranes, and probed with antibodies indicated at the bottom of each blot directed against NHE1, Na+/K+-ATPase, TfR, or COXI.

NHE1 reduction in the myocardium upon shRNA-NHE1 transduction was further investigated in pure membrane preparations isolated from left ventricular muscle of rats injected with shRNA-SCR or shRNA-NHE1. One month after transduction, membrane NHE1 expression was also reduced by 55 ± 7% (n = 4) in rats transduced with shRNA-NHE1 compared with shRNA-SCR-transduced rats (100 ± 7%, n = 3). Therefore, we corroborated that transduction of shRNA-NHE1 in the rat myocardium has the ability to reduce the expression of mNHE1 and membrane NHE1 to the same extent.

We conclude that stable expression of shRNA-NHE1 delivered with a lentiviral-based vector system significantly reduced the expression of NHE1 protein in mitochondria. Thus we confirmed the expression of the NHE1 Na+/H+ exchanger in the subcellular organelle.

**Functional role of NHE1 in mitochondria.** Induction of the MPTP has been implicated in cellular apoptosis and in I/R injury. Shortly after myocardial ischemia, the MPTP, a channel in mitochondrial membrane, opens and causes isolated mitochondria to swell. Measurements of Ca2⁺–induced mitochondrial swelling were initially tested here in deenergized mitochondria isolated from rat hearts transduced with either shRNA-SCR or shRNA-NHE1 (Fig. 8A). Step addition of 50 μM CaCl₂ induced a small decrease in light scattering, at each step, in shRNA-SCR-transduced rats that was attenuated by the NHE1 inhibitor HOE-642 (10 μM, cariporide). The decrease in light scattering was, however, blunted in shRNA-NHE1-transduced animals, and no additional effect was observed with the addition of cariporide. To characterize further the role of NHE1 in mitochondria, animals were transduced with shRNA-SCR (nonsilencing control, n = 3), or transduced with shRNA-NHE1 (n = 4). One month after transduction, mitochondria were isolated from left ventricular myocardium, and mitochondrial suspensions were exposed to 200 μM CaCl₂, which is known to induce MPT opening with the consequent mitochondrial swelling (6, 21) (Fig. 8, B and C). If the MPTP is open after the Ca2⁺ addition, solutes will be free to enter the matrix, causing the mitochondria to swell. These changes are observed as decreases in light scattering. Light scattering decrease was calculated for each sample by taking the difference between the values before and after the addition of CaCl₂. The decrease in light scattering induced by Ca2⁺ addition to mitochondria is used as an indication of mitochondrial swelling. In rats transduced with shRNA-SCR, addition of 200 μM CaCl₂ evoked a large decrease in light scattering (Fig. 8B). Conversely, rats transduced with shRNA-NHE1 showed little decrease in light scattering and a significant reduction in mitochondrial swelling, 36 ± 4% (7 mitochondrial suspensions), compared with scrambled control, 100 ± 4% (6 mitochondrial suspensions). Interestingly, inhibition of NHE1 with cariporide decreased Ca2⁺–induced mitochondrial swelling in rats transduced with shRNA-SCR, 63 ± 6% (4 mitochondrial suspensions), providing evidence for a direct mitochondrial action of the NHE1. Cariporide did not, however, further decrease mitochondrial swelling in rats transduced with shRNA-NHE1, 33 ± 6% (3 mitochondrial suspensions). Fail-

NHE, Na\textsuperscript{+}/H\textsuperscript{+} exchanger; COX1, cytochrome c oxidase complex I. NH\textsubscript{2}-terminal protein regions supporting a mitochondrial targeting sequence and their cleavage site obtained with the MITOPROT Software (http://ihg2.helmholtzmuenchen.de/ihg/mitoprot.html). Protein sequences were retrieved from the SwissProt Database.

We conclude that NHE1 plays a functional role in heart mitochondria and that the MPTP opening and subsequent mitochondria volume increase triggered by CaCl\textsubscript{2} is due, at least in part, to the mNHE1.

MNHE1 would catalyze the H\textsuperscript{+} influx into the mitochondria, regulating mitochondrial matrix pH homeostasis, playing a role in mitochondrial metabolism, and being a factor in determining MPTP opening. Although we have not ruled out the expression of NHE6 (MITOPROT analysis, Table 1), the NHE1 seems to be the isoform involved in the delay of the MPTP opening.

**DISCUSSION**

In 1969, Mitchell and Moyle (42) proposed the existence of Na\textsuperscript{+}/H\textsuperscript{+} exchange in mitochondria and Garlid et al. (24) in 1991 demonstrated in beef heart mitochondria that solubilized NHE in the organelle can be purified in an active state. In mitochondria, NHE mediates the exchange of Na\textsuperscript{+} for intermembrane H\textsuperscript{+} generated by respiration (23). Thus H\textsuperscript{+} influx in the mitochondrial matrix through the mitochondrial NHE would constitute a form of H\textsuperscript{+} leakage not coupled to ATP synthesis, which in turn will dissipate the energy stored as transmembrane H\textsuperscript{+} gradient.

NHE1 is a typical integral membrane protein with 10–12 predicted spanning segments, a long COOH terminus, and an...
NH₂-terminal tail that possesses the mitochondrial localization signal. Besides the expression of NHE1 in the plasma membrane of cardiac cells, herein we have characterized the expression of NHE1 in mitochondria of cardiac muscle. Recently, the expression of NHE1 was suggested in Percoll-purified rat heart mitochondria by immunoblot analysis (32).

In addition to characterizing the localization of NHE1 in the heart mitochondria, we report one major functional role: the increase in threshold to open the MPTP in rat heart deficient in NHE1.

The dual localization pattern displayed by NHE1 is somehow surprising although not unique among other membrane proteins. Other studies have reported the presence of Kv1.3 (53), Kir6.2 (22), and Ca²⁺-activated BK potassium channels (51), NCX1–3 (25), and CX43 (8, 9) in the plasma and mitochondrial membranes. Unlike NHE1 (MITOPROT Software, Tables 1 and 2), all of these channels did not exhibit classical basic NH₂-terminal mitochondrial targeting sequences but are targeted to mitochondrial inner membranes by unknown mechanisms. Several mitochondrial proteins of the inner membrane characterized by many highly hydrophobic transmembrane segments, similar to NHE1, and that lack the NH₂-terminal sequence become imported into the mitochondria in a Tim22 complex-dependent pathway (56). The sorting and targeting information seems to comprise several distant amino acids spread throughout the mature protein and is hardly recognizable (11, 17). Although specific posttranslational protein modifications and differential splicing have been considered to account for organellar protein targeting, the mechanisms responsible for the simultaneous targeting of a protein (NHE1) to different cellular compartments (plasma membrane, mitochondria) are not known and are beyond the focus of the present study.

Emerging evidence supports the fact that mitochondrial dysfunction underlies the causes of numerous cardiac diseases [for review, see Baines (5)]. Studies on the MPTP and its role in reperfusion injury and cardiac hypertrophy have proven fruitful (27, 45). Griffith and Hallestrap (26) and Duchen et al. (18) first showed that delayed opening of MPTP by CsA protects I/R injury in perfused rat hearts. Recently, Piot et al. (45) reported in humans with acute myocardial infarction the decrease in infarct size by the MPTP inhibitor CsA administrated at the time of reperfusion. Interestingly, a role of mitochondria in determining cardiac hypertrophy after myocardial infarction has also been proposed (12, 15, 30, 33, 34).

NHE1 inhibition was one of the most promising therapeutic strategies for I/R injury based on experimental animal studies.
Controversial results, however, were obtained using NHE1 inhibitors in clinical trials: cariporide (GUARDIAN) (55) or EXPEDITION (41) and Eniporide (ESCAMI) (59) [for review, see Murphy and Allen (43)]. These trials were unable to demonstrate a significant reduction in mortality when these compounds were tested in patients after acute myocardial infarction (55, 59) or were suspended early due to undesired cerebrovascular side effects (41). Yet, in a subgroup of patients who underwent coronary artery bypass graft surgery, a 25% improvement in cardiac performance was detected with cariporide. Similar beneficial effects were seen in a small trial of 100 patients who received cariporide before percutaneous coronary angioplasty (49).

The related myocardial protective effects induced by cyclosporine and NHE1 inhibition prompted us to speculate about the possibility that NHE1 inhibition protects the heart by targeting previously primed mitochondria (46).

Since the seminal paper by Karmazyn (34) showing that NHE1 inhibition protects the isolated heart from I/R injury, followed by numerous experimental studies (19, 37, 57), and ending in clinical trials (49, 55), the effects of NHE1 inhibition were analyzed without considering a mitochondrial effect. Only a report by Ruiz Meana et al. (48) drew attention to this possibility. In connection with this, Teshima and collaborators (54) demonstrated that cariporide protects cardiomyocyte death induced by oxidative stress, preventing cytosolic Na⁺/H⁺ and Ca²⁺/H⁺ accumulation and mitochondrial Ca²⁺ overload, and preserving mitochondrial ATPase. Although these effects were proposed to be secondary to prevention of the cytosolic increase in Ca²⁺, more recently a direct mitochondrial action of NHE1 inhibitors, which decrease myocardial superoxide production, was reported (21). A “cyclosporine like effect” of NHE1 inhibition was proposed, but the site of action of those compounds was not identified (21).

A mitochondrial action of NHE1 inhibition secondary to changes in cytosol was previously reported by Javadov et al. (31). Those authors were unable to detect changes in isolated mitochondria perhaps because of the controlled Ca²⁺...
gradients in the mitochondria and suggested an action on MPTP function through glycogen synthase kinase 3β (33). Although we cannot rule out changes in this kinase, our similar and not additive results obtained in isolated mitochondria with inhibition and silencing of the mNHE1 limit the discussion.

We have demonstrated that we were able to knock down the expression of NHE1 expressed in membrane fractions of either sarcolemmal or mitochondrion by direct intramyocardial injections of shRNA-NHE1 in rats (Fig. 7). Intramyocardial injection of lentivirus carrying a shRNA-NHE1 not only reduced the expression of NHE1 at the level of mitochondria but also prevented Ca2+-induced swelling of rat heart mitochondria (Figs. 7 and 8 and Supplemental Fig. 1).

A decrease in mitochondrial exchanger function (or reduced expression by siRNA) should increase H+ concentration on the external side of the MPTP. In connection with this, the pre-

Fig. 8. CaCl2-induced swelling of rat heart mitochondria. A: sample scattered light absorbance traces of Ca2+-induced swelling in response to step addition of CaCl2 (50 μM, bars over text) for heart mitochondria isolated from rats transduced with shRNA-NHE1 or with shRNA-SCR (SCR, scrambled, control) in the presence or absence of cariporide (HOE-642, 10 μM). B: typical experiment showing that shRNA-NHE1 transduction (3 rats, 7 mitochondrial suspensions) significantly inhibited Ca2+-induced mitochondrial swelling and the decrease in light scattering of mitochondrial suspensions compared with SCR-transduced animals (3 rats, 6 mitochondrial suspensions). Cariporide attenuated the decrease in light scattering in SCR-transduced rats (3 rats, 4 mitochondrial suspensions) and did not affect the decrease in light scattering in shRNA-NHE1-transduced rats (3 rats, 3 mitochondrial suspensions). C: summary results of light scattering decrease in rats transduced with shRNA-SCR or with shRNA-NHE1, before and after treatment with 10 μM HOE-642. The fact that shRNA-NHE1 have a more profound effect on mitochondrial swelling compared with 10 μM HOE suggests that probably the HOE dose used here was not sufficient to achieve maximal inhibition. *P < 0.05 vs. SCR and **P < 0.05 vs. SCR + 10 μM HOE-642 (ANOVA).
vention of MPTP formation by acidosis in reperfusion after ischemia has been reported (16, 47). MPTP opening can be further increased when Ca2+ overload is associated by oxidative stress. Moreover, a decrease in mitochondrial anion superoxide production induced by two known enhancers of reactive oxygen species (ROS) production, ANG II and endothelin-1, upon NHE1 inhibition has been reported (21). Furthermore, the increase in ROS production induced by the opening of mitochondrial ATP-dependent K+ was abolished by cariporide (21).

We are reporting a delay of MPTP formation in isolated mitochondria by NHE1 inhibition and posttranscriptional NHE1 gene silencing. These findings open a new avenue of research about the mechanism of protection achieved by NHE1 inhibition either in reperfusion injury or in cardiac hypertrophy and failure.
